

TLV2553 12-Bit, 200-KSPS, 11-Channel, Low-Power, Serial ADC

1 Features

- 12-Bit-Resolution A/D Converter
- Up to 200 KSPS (150 KSPS for 3 V) Throughput Over Operating Temperature Range With 12-Bit Output Mode
- 11 Analog Input Channels
- 3 Built-In Self-Test Modes
- Inherent Sample and Hold Function
- Linearity Error, ± 1 LSB Maximum
- On-Chip Conversion Clock
- Unipolar or Bipolar Output Operation
- Programmable MSB or LSB First
- Programmable Power Down
- Programmable Output Data Length
- SPI Compatible Serial Interface With I/O Clock Frequencies up to 15 MHz (CPOL=0, CPHA=0)

2 Applications

- Process Control
- Portable Data Logging
- Battery-Powered Instruments

3 Description

The TLV2553 is a 12-bit, switched-capacitor, successive-approximation, analog-to-digital converter. The ADC has three control inputs [chip select (\overline{CS}), the input-output clock, and the address/control input (DATAIN)], designed for communication with the serial port of a host processor or peripheral through a serial 3-state output.

In addition to the high-speed converter and versatile control capability, the device has an on-chip 14-channel multiplexer that can select any one of 11 inputs or any one of three internal self-test voltages using configuration register 1. The sample-and-hold function is automatic. At the end of conversion, when programmed as EOC, the pin 19 output goes high to indicate that conversion is complete. The converter incorporated in the device features differential, high-impedance reference inputs that facilitate ratiometric conversion, scaling, and isolation of analog circuitry from logic and supply noise. A switched-capacitor design allows low-error conversion over the full operating temperature range.

The TLV2553I is characterized for operation from $T_A = -40^\circ\text{C}$ to 85°C .

Device Information⁽¹⁾

PART NUMBER	PACKAGE	BODY SIZE (NOM)
TLV2553IPW	TSSOP (20)	6.50 mm x 4.40 mm
TLV2553IDW	SOIC (20)	12.80 mm x 7.50 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
AIN0 to AIN10	1 to 9, 11, 12	I	Analog input. These 11 analog-signal inputs are internally multiplexed.
$\overline{\text{CS}}$	15	I	Chip select. A high-to-low transition on $\overline{\text{CS}}$ resets the internal counters and controls and enables DATA OUT, DATA IN, and I/O CLOCK. A low-to-high transition disables DATA IN and I/O CLOCK within a setup time.
DATA IN	17	I	Serial data input. The 4-bit serial data can be used as address selects the desired analog input channel or test voltage to be converted next, or a command to activate other features. The input data is presented with the MSB (D7) first and is shifted in on the first four rising edges of the I/O CLOCK. After the four address/command bits are read into the command register CMR, I/O CLOCK clocks the remaining four bits of configuration in.
DATA OUT	16	O	3-state serial output for the A/D conversion result. DATA OUT is in the high-impedance state when $\overline{\text{CS}}$ is high and active when $\overline{\text{CS}}$ is low. With a valid $\overline{\text{CS}}$, DATA OUT is removed from the high-impedance state and is driven to the logic level corresponding to the MSB/LSB value of the previous conversion result. The next falling edge of I/O CLOCK drives DATA OUT to the logic level corresponding to the next MSB/LSB, and the remaining bits are shifted out in order.
EOC	19	O	End-of-conversions status. Used to indicate the end of conversion (EOC) to the host processor. EOC goes from a high to a low logic level after the falling edge of the last I/O CLOCK and remains low until the conversion is complete and the data is ready for transfer.
GND	10	—	Ground. GND is the ground return terminal for the internal circuitry. Unless otherwise noted, all voltage measurements are with respect to GND.
I/O CLOCK	18	I	Input /output clock. I/O CLOCK receives the serial input and performs the following four functions: <ol style="list-style-type: none"> 1. It clocks the eight input data bits into the input data register on the first eight rising edges of I/O CLOCK with the multiplexer address available after the fourth rising edge. 2. On the fourth falling edge of I/O CLOCK, the analog input voltage on the selected multiplexer input begins charging the capacitor array and continues to do so until the last falling edge of I/O CLOCK. 3. The remaining 11 bits of the previous conversion data are shifted out on DATA OUT. Data changes on the falling edge of I/O CLOCK. 4. Control of the conversion is transferred to the internal state controller on the falling edge of the last I/O CLOCK.
REF+	14	I/O	Positive reference voltage The upper reference voltage value (nominally V _{CC}) is applied to REF+. The maximum analog input voltage range is determined by the difference between the voltage applied to terminals REF+ and REF-.
REF-	13	I/O	Negative reference voltage. The lower reference voltage value (nominally ground) is applied to REF-. This pin is connected to analog ground (GND of the ADC) when internal reference is used.
V _{CC}	20	—	Positive supply voltage

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
V _{CC}	Supply voltage ⁽²⁾	-0.5	6.5	V
V _I	Input voltage (any input)	-0.3	V _{CC} + 0.3	
V _O	Output voltage	-0.3	V _{CC} + 0.3	
V _{ref+}	Positive reference voltage	-0.3	V _{CC} + 0.3	
V _{ref-}	Negative reference voltage	-0.3	V _{CC} + 0.3	
I _I	Peak input current (any input)	-20	20	mA
	Peak total input current (all inputs)	-30	30	
T _J	Operating virtual junction temperature	-40	150	°C
T _A	Operating free-air temperature	-40	85	
T _{stg}	Storage temperature	-65	150	

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) All voltage values are with respect to the GND terminal with REF– and GND wired together (unless otherwise noted).

6.2 ESD Ratings

		VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

			MIN	NOM	MAX	UNIT
V _{CC}	Supply voltage		2.7		5.5	V
I/O CLOCK	I/O CLOCK frequency	V _{CC} = 4.5 V to 5.5 V	16-bit I/O	0.01	15	MHz
			12-bit I/O	0.01	15	
			8-bit I/O	0.01	15	
		V _{CC} = 2.7 V to 3.6 V	0.01	10		
I/O CLOCK	Tolerable clock jitter	V _{CC} = 4.5 V to 5.5 V			0.38	ns
	Aperture jitter	V _{CC} = 4.5 V to 5.5 V		100		ps
I/O CLOCK	Analog input voltage ⁽¹⁾	V _{CC} = 4.5 V to 5.5 V	0	(REF+) – (REF–)		V
		V _{CC} = 3 V to 3.6 V	0	(REF+) – (REF–)		
		V _{CC} = 2.7 V to 3 V	0	(REF+) – (REF–)		
V _{IH}	High-level control input voltage	V _{CC} = 4.5 V to 5.5 V	2			V
		V _{CC} = 2.7 V to 3.6 V	2.1			
V _{IL}	Low-level control input voltage	V _{CC} = 4.5 V to 5.5 V			0.8	V
		V _{CC} = 2.7 V to 3.6 V			0.6	
T _A	Operating free-air temperature	TLV2553I	–40		85	°C

(1) Analog input voltages greater than the voltage applied to REF+ convert as all ones (111111111111), while input voltages less than the voltage applied to REF– convert as all zeros (000000000000).

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾	TLV2553		UNIT	
	DW (SOIC)	PW (TSSOP)		
	20 PINS	20 PINS		
R _{θJA}	Junction-to-ambient thermal resistance	66	88.1	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	31.4	21.6	°C/W
R _{θJB}	Junction-to-board thermal resistance	33.7	40.4	°C/W
ψ _{JT}	Junction-to-top characterization parameter	7.4	0.8	°C/W
ψ _{JB}	Junction-to-board characterization parameter	33.3	39.7	°C/W

(1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report, [SPRA953](#).

6.5 Electrical Characteristics

over recommended operating free-air temperature range, when $V_{CC} = 5\text{ V}$: $V_{REF+} = 5\text{ V}$, I/O CLOCK frequency = 15 MHz, when $V_{CC} = 2.7\text{ V}$: $V_{REF+} = 2.5\text{ V}$, I/O CLOCK frequency = 10 MHz (unless otherwise noted)

PARAMETER		TEST CONDITIONS		MIN	TYP ⁽¹⁾	MAX	UNIT
V_{OH}	High-level output voltage	$V_{CC} = 4.5\text{ V}$, $I_{OH} = -1.6\text{ mA}$	30 pF	2.4		V	
		$V_{CC} = 2.7\text{ V}$, $I_{OH} = -0.2\text{ mA}$		$V_{CC} - 0.1$			
V_{OL}	Low-level output voltage	$V_{CC} = 4.5\text{ V}$, $I_{OL} = -1.6\text{ mA}$	30 pF	0.4		V	
		$V_{CC} = 2.7\text{ V}$, $I_{OL} = -0.8\text{ mA}$		0.1			
I_{OZ}	High-impedance off-state output current	$V_O = V_{CC}$, $\overline{CS} = V_{CC}$		1	2.5	μA	
		$V_O = 0\text{ V}$, $\overline{CS} = V_{CC}$		-1	-2.5		
I_{CC}	Operating supply current	$\overline{CS} = 0\text{ V}$, External reference	$V_{CC} = 5\text{ V}$	1.2		mA	
			$V_{CC} = 2.7\text{ V}$	0.9			
$I_{CC(PD)}$	Power-down current	For all digital inputs, $0 \leq V_I \leq 0.5\text{ V}$ or $V_I \geq V_{CC} - 0.5\text{ V}$, I/O CLOCK = 0 V	Software power down	0.1	1	μA	
			Auto power down	0.1	10		
I_{IH}	High-level input current	$V_I = V_{CC}$		0.005	2.5	μA	
I_{IL}	Low-level input current	$V_I = 0\text{ V}$		-0.005	-2.5	μA	
I_{lkg}	Selected channel leakage current	Selected channel at V_{CC} , Unselected channel at 0 V		1		μA	
		Selected channel at 0 V, Unselected channel at V_{CC}		-1			
f_{OSC}	Internal oscillator frequency	$V_{CC} = 4.5\text{ V to } 5.5\text{ V}$		3.27		MHz	
		$V_{CC} = 2.7\text{ V to } 3.6\text{ V}$		2.56			
$t_{convert}$	Conversion time ($13.5 \times (1/f_{OSC}) + 25\text{ ns}$)	$V_{CC} = 4.5\text{ V to } 5.5\text{ V}$		4.15		μs	
		$V_{CC} = 2.7\text{ V to } 3.6\text{ V}$		5.54			
Internal oscillator frequency voltage				3.6	4.1	V	
Z_i	Input impedance ⁽²⁾	Analog inputs	$V_{CC} = 4.5\text{ V}$	500		Ω	
			$V_{CC} = 2.7\text{ V}$	600			
C_i	Input capacitance	Analog inputs	45		55	pF	
		Control inputs	5		15		

(1) All typical values are at $V_{CC} = 5\text{ V}$, $T_A = 25^\circ\text{C}$.

(2) The switch resistance is very nonlinear and varies with input voltage and supply voltage. This is the worst case.

6.6 External Reference Specifications

PARAMETER	TEST CONDITIONS	MIN	TYP ⁽¹⁾	MAX	UNIT
REF– Reference input voltage	V _{CC} = 4.5 V to 5.5 V	–0.1	0	0.1	V
	V _{CC} = 2.7 V to 3.6 V	–0.1	0	0.1	
REF+ Reference input voltage	V _{CC} = 4.5 V to 5.5 V	2		V _{CC}	V
	V _{CC} = 2.7 V to 3.6 V	2		V _{CC}	
External reference input voltage difference, (REF+) – (REF–) ⁽²⁾	V _{CC} = 4.5 V to 5.5 V	1.9		V _{CC}	V
	V _{CC} = 2.7 V to 3.6 V	1.9		V _{CC}	
External reference supply current	\overline{CS} at 0 V	V _{CC} = 4.5 V to 5.5 V		0.94	mA
		V _{CC} = 2.7 V to 3.6 V		0.62	
Reference input impedance	V _{CC} = 5 V	Static	1		MΩ
		During sampling/conversion	6	9	kΩ
	V _{CC} = 2.7 V	Static	1		MΩ
		During sampling/conversion	6	9	kΩ

(1) All typical values are at T_A = 25°C.

(2) Add a 0.1-μF capacitor between REF+ and REF– pins when external reference is used.

6.7 Operating Characteristics

over recommended operating free-air temperature range, V_{REF+} = 5 V, I/O CLOCK frequency = 15 MHz when V_{CC} = 5 V, V_{REF+} = 2.5 V, I/O CLOCK frequency = 10 MHz when V_{CC} = 2.7 V (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP ⁽¹⁾	MAX	UNIT
INL Integral linearity error ⁽²⁾		–1		1	LSB
DNL Differential linearity error		–1		1	LSB
E _O Offset error ⁽³⁾	See ⁽⁴⁾	–2		2	mV
E _Q Gain error ⁽³⁾	See ⁽⁴⁾	–3		3	mV
E _T Total unadjusted error ⁽⁵⁾			±15		LSB
Self-test output code Table 2 , ⁽⁶⁾	Address data input = 1011		2048		
	Address data input = 1100		0		
	Address data input = 1101		4095		

(1) All typical values are at T_A = 25°C.

(2) Linearity error is the maximum deviation from the best straight line through the A/D transfer characteristics.

(3) Gain error is the difference between the actual midstep value and the nominal midstep value in the transfer diagram at the specified gain point after the offset error has been adjusted to zero. Offset error is the difference between the actual midstep value and the nominal midstep value at the offset point.

(4) Analog input voltages greater than the voltage applied to REF+ convert as all ones (1111111111), while input voltages less than the voltage applied to REF– convert as all zeros (0000000000).

(5) Total unadjusted error comprises linearity, zero-scale, and full-scale errors.

(6) Both the input address and the output codes are expressed in positive logic.

6.8 Timing Requirements: $V_{REF+} = 5\text{ V}$

over recommended operating free-air temperature range, I/O CLOCK frequency = 15 MHz, $V_{CC} = 5\text{ V}$, load = 25 pF (unless otherwise noted)

		MIN	TYP	MAX	UNIT
t_{w1}	Pulse duration I/O CLOCK high or low	26.7		100000	ns
t_{su1}	Setup time DATA IN valid before I/O CLOCK rising edge (see Figure 32)	12			ns
t_{h1}	Hold time DATA IN valid after I/O CLOCK rising edge (see Figure 32)	0			ns
t_{su2}	Setup time \overline{CS} low before first rising I/O CLOCK edge ⁽¹⁾ (see Figure 33)	25			ns
t_{h2}	Hold time \overline{CS} pulse duration high time (see Figure 33)	100			ns
t_{h3}	Hold time \overline{CS} low after last I/O CLOCK falling edge (see Figure 33)	0			ns
t_{h4}	Hold time DATA OUT valid after I/O CLOCK falling edge (see Figure 34)	2			ns
t_{h5}	Hold time \overline{CS} high after EOC rising edge when \overline{CS} is toggled (see Figure 37)	0			ns
t_{d1}	Delay time \overline{CS} falling edge to DATA OUT valid (MSB or LSB) (see Figure 31)	Load = 25 pF		28	ns
		Load = 10 pF		20	ns
t_{d2}	Delay time \overline{CS} rising edge to DATA OUT high impedance (see Figure 31)			10	ns
t_{d3}	Delay time I/O CLOCK falling edge to next DATA OUT bit valid (see Figure 34)	2		20	ns
t_{d4}	Delay time Last I/O CLOCK falling edge to EOC falling edge			55	ns
t_{d5}	Delay time last I/O CLOCK falling edge to \overline{CS} falling edge to abort conversion			1.5	μs
t_{t1}	Transition time I/O CLOCK ⁽¹⁾ (see Figure 34)			1	μs
t_{t2}	Transition time DATA OUT (see Figure 34)			5	ns
t_{t3}	Transition time \overline{INT}/EOC , C_L at 7 pF (see Figure 36)			2.4	ns
t_{t4}	Transition time DATA IN, \overline{CS}			10	μs
t_{cycle}	Total cycle time (sample, conversion and delays) ⁽¹⁾			$\text{MAX}(t_{\text{convert}}) + \text{I/O period} (8/12/16 \text{ CLKs})$	μs
t_{sample}	Channel acquisition time (sample), at 1 k Ω , ⁽¹⁾ (See Figure 1 through Figure 6)	Source impedance = 25 Ω	600		ns
		Source impedance = 100 Ω	650		
		Source impedance = 500 Ω	700		
		Source impedance = 1 k Ω	1000		

(1) I/O CLOCK period = 8X [1/(I/O CLOCK frequency)] or 12X [1/(I/O CLOCK frequency)] or 16X [1/(I/O CLOCK frequency)] depends on I/O format selected.

6.9 Timing Requirements: $V_{REF+} = 2.5 V$

over recommended operating free-air temperature range, I/O CLOCK frequency = 10 MHz, $V_{CC} = 2.7 V$, load = 25 pF (unless otherwise noted)

		MIN	TYP	MAX	UNIT
t_{w1}	Pulse duration I/O CLOCK high or low	40		100000	ns
t_{su1}	Setup time DATA IN valid before I/O CLOCK rising edge (see Figure 32)	22			ns
t_{h1}	Hold time DATA IN valid after I/O CLOCK rising edge (see Figure 32)	0			ns
t_{su2}	Setup time \overline{CS} low before first rising I/O CLOCK edge ⁽¹⁾ (see Figure 33)	33			ns
t_{h2}	Hold time \overline{CS} pulse duration high time (see Figure 33)	100			ns
t_{h3}	Hold time \overline{CS} low after last I/O CLOCK falling edge (see Figure 33)	0			ns
t_{h4}	Hold time DATA OUT valid after I/O CLOCK falling edge (see Figure 33)	2			ns
t_{h5}	Hold time \overline{CS} high after EOC rising edge when \overline{CS} is toggled (see Figure 37)	0			ns
t_{d1}	Delay time \overline{CS} falling edge to DATA OUT valid (MSB or LSB) (see Figure 31)	Load = 25 pF		30	ns
		Load = 10 pF		22	ns
t_{d2}	Delay time \overline{CS} rising edge to DATA OUT high impedance (see Figure 31)			10	ns
t_{d3}	Delay time I/O CLOCK falling edge to next DATA OUT bit valid (see Figure 34)	2		33	ns
t_{d4}	Delay time Last I/O CLOCK falling edge to EOC falling edge			75	ns
t_{d5}	Delay time last I/O CLOCK falling edge to \overline{CS} falling edge to abort conversion			1.5	μs
t_{t1}	Transition time I/O CLOCK ⁽¹⁾ (see Figure 34)			1	μs
t_{t2}	Transition time DATA OUT (see Figure 34)			5	ns
t_{t3}	Transition time \overline{INT}/EOC , C_L at 7 pF (see Figure 36)			4	ns
t_{t4}	Transition time DATA IN, \overline{CS}			10	μs
t_{cycle}	Total cycle time (sample, conversion and delays) ⁽¹⁾			MAX($t_{convert}$) + I/O period (8/12/16 CLKs)	μs
t_{sample}	Channel acquisition time (sample), at 1 k Ω , ⁽¹⁾ (See Figure 1 through Figure 6)	Source impedance = 25 Ω	800		ns
		Source impedance = 100 Ω	850		
		Source impedance = 500 Ω	1000		
		Source impedance = 1 k Ω	1600		

(1) I/O CLOCK period = 8X [1/(I/O CLOCK frequency)] or 12X [1/(I/O CLOCK frequency)] or 16X [1/(I/O CLOCK frequency)] depends on I/O format selected.

Figure 1. Timing for 12-Clock Transfer Using \overline{CS} With DATA OUT Set for MSB First

NOTE: To minimize errors caused by noise at \overline{CS} , the internal circuitry waits for a setup time after the \overline{CS} falling edge before responding to control input signals. Therefore, no attempt should be made to clock in an address until the minimum \overline{CS} setup time has elapsed.

Figure 2. Timing for 12-Clock Transfer Not Using \overline{CS} With DATA OUT Set for MSB First

Figure 3. Timing for 8-Clock Transfer Using \overline{CS} With DATA OUT Set for MSB First

NOTE: To minimize errors caused by noise at \overline{CS} , the internal circuitry waits for a setup time after the \overline{CS} falling edge before responding to control input signals. Therefore, no attempt should be made to clock in an address until the minimum \overline{CS} setup time has elapsed.

8 Detailed Description

8.1 Overview

Initially, with chip select (\overline{CS}) high, I/O CLOCK and DATA IN are disabled and DATA OUT is in the high-impedance state. \overline{CS} going low begins the conversion sequence by enabling I/O CLOCK and DATA IN and removes DATA OUT from the high-impedance state. The input data is an 8-bit data stream consisting of a 4-bit address or command (D7–D4) and a 4-bit configuration data (D3–D0). Configuration register 1, CFGR1, which controls output data format configuration, consists of a 2-bit data length select (D3–D2), an output MSB or LSB first bit (D1), and a unipolar or bipolar output select bit (D0) that are applied to any command (from DATA IN) except for command 1111b. The I/O CLOCK sequence applied to the I/O CLOCK terminal transfers this data to the input data register. During this transfer, the I/O CLOCK sequence also shifts the previous conversion result from the output data register to DATA OUT. I/O CLOCK receives the input sequence of 8, 12, or 16 clock cycles long depending on the data-length selection in the input data register. Sampling of the analog input begins on the fourth falling edge of the input I/O CLOCK sequence and is held after the last falling edge of the I/O CLOCK sequence. The last falling edge of the I/O CLOCK sequence also takes EOC low and begins the conversion.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Analog MUX

The 11 analog inputs, three internal voltages, and power-down mode are selected by the input multiplexer according to the input addresses shown in [Table 2](#). The input multiplexer is a break-before-make type to reduce input-to-input noise rejection resulting from channel switching. Sampling of the analog input starts on the falling edge of the fourth I/O CLOCK and continues for the remaining I/O CLOCK pulses. The sample is held on the falling edge of the last I/O CLOCK pulse. The three internal test inputs are applied to the multiplexer, then sampled and converted in the same manner as the external analog inputs. The first conversion after the device has returned from the power-down state may not read accurately due to internal device settling.

Feature Description (continued)

8.3.2 Reference

An external reference can be used through two reference input pins, REF+ and REF-. The voltage levels applied to these pins establish the upper and lower limits of the analog inputs to produce a full-scale and zero-scale reading respectively. The values of REF+, REF-, and the analog input should not exceed the positive supply or be lower than GND consistent with the specified absolute maximum ratings. The digital output is at full scale when the input signal is equal to or higher than REF+ and at zero when the input signal is equal to or lower than REF-.

Figure 39. Reference Block Diagram

8.4 Device Functional Modes

8.4.1 Converter Operation

The operation of the converter is organized as a succession of three distinct cycles: 1) the data I/O cycle, 2) the sampling cycle and 3) the conversion cycle. The first two are partially overlapped.

8.4.2 Data I/O Cycle

The data I/O cycle is defined by the externally provided I/O CLOCK and lasts 8, 12, or 16 clock periods, depending on the selected output data length. During the I/O cycle, the following two operations take place simultaneously. An 8-bit data stream consisting of address/command and configuration information is provided to DATA IN. This data is shifted into the device on the rising edge of the first eight I/O CLOCK clocks. DATA INPUT is ignored after the first eight clocks during 12- or 16-clock I/O transfers. The data output, with a length of 8, 12, or 16 bits, is provided serially on DATA OUT. When \overline{CS} is held low, the first output data bit occurs on the rising edge of EOC. When \overline{CS} is toggled between conversions, the first output data bit occurs on the falling edge of \overline{CS} . This data is the result of the previous conversion period, and after the first output data bit, each succeeding bit is clocked out on the falling edge of each succeeding I/O CLOCK.

8.4.3 Sampling Cycle

During the sampling cycle, one of the analog inputs is internally connected to the capacitor array of the converter to store the analog input signal. The converter starts sampling the selected input immediately after the four address/command bits have been clocked into the input data register. Sampling starts on the fourth falling edge of I/O CLOCK. The converter remains in the sampling mode until the eighth, twelfth, or sixteenth falling edge of the I/O CLOCK depending on the data-length selection.

Device Functional Modes (continued)

After the 8-bit data stream has been clocked in, DATA IN should be held at a fixed digital level until EOC goes high (indicating that the conversion is complete) to maximize the sampling accuracy and minimize the influence of external digital noise.

8.4.4 Conversion Cycle

A conversion cycle is started only after the I/O cycle is completed, which minimizes the influence of external digital noise on the accuracy of the conversion. This cycle is transparent to the user because it is controlled by an internal clock (oscillator). The total conversion time is equal to 13.5 OSC clocks plus a small delay (approximately 125 ns) to start the OSC. During the conversion period, the device performs a successive-approximation conversion on the analog input voltage.

EOC goes low at the start of the conversion cycle and goes high when the conversion is complete and the output data register is latched. After EOC goes low, the analog input can be changed without affecting the conversion result. Because the delay from the falling edge of the last I/O CLOCK to the falling edge of EOC is fixed, any time-varying analog input signals can be digitized at a fixed rate without introducing systematic harmonic distortion or noise due to timing uncertainty.

8.4.5 Power Up and Initialization

After power up, \overline{CS} must be taken from high to low to begin an I/O cycle. The EOC pin is initially high, and the configuration register is set to all zeroes. The contents of the output data register are random, and the first conversion result should be ignored. To initialize during operation, CS is taken high and is then returned low to begin the next I/O cycle. The first conversion after the device has returned from the power-down state may not read accurately due to internal device settling.

Table 1. Operational Terminology

TERMINOLOGY	DESCRIPTION
Current (N) I/O cycle	The entire I/O CLOCK sequence that transfers address and control data into the data register and clocks the digital result from the previous conversion from DATA OUT.
Current (N) conversion cycle	The conversion cycle starts immediately after the current I/O cycle. The end of the current I/O cycle is the last clock falling edge in the I/O CLOCK sequence. The current conversion result is loaded into the output register when conversion is complete.
Current (N) conversion result	The current conversion result is serially shifted out on the next I/O cycle.
Previous (N-1) conversion cycle	The conversion cycle just before the current I/O cycle
Next (N+1) I/O cycle	The I/O period that follows the current conversion cycle

8.4.5.1 Example

In 12-bit mode, the result of the current conversion cycle is a 12-bit serial-data stream clocked out during the next I/O cycle. The current I/O cycle must be exactly 12 bits long to maintain synchronization, even when this corrupts the output data from the previous conversion. The current conversion is begun immediately after the twelfth falling edge of the current I/O cycle.

8.4.6 Data Input

The data input is internally connected to an 8-bit serial-input address and control register. The register defines the operation of the converter and the output data length. The host provides the input data byte with the MSB first. Each data bit is clocked in on the rising edge of the I/O CLOCK sequence (see [Table 2](#) for the data input-register format).

Table 2. Command Set (CMR) and Configuration

SDI D[7:4]		COMMAND	CFGR1	
Binary	HEX		SDI D[3:0]	CONFIGURATION
0000b	0h	SELECT analog input channel 0	D[3:2]	01: 8-bit output length X0: 12-bit output length (see Note) 11: 16-bit output length
0001b	1h	SELECT analog input channel 1	D1	0: MSB out first 1: LSB out first
0010b	2h	SELECT analog input channel 2	D0	0: Unipolar binary 1: Bipolar 2s complement

1111b	Fh	Reserved		

8.4.7 Data Input—Address/Command Bits

The four MSBs (D7–D4) of the input data register are the address or command. These can be used to address one of the 11 input channels, address one of three reference-test voltages, or activate software power-down mode. All address/command bits affect the current conversion, which is the conversion that immediately follows the current I/O cycle. They also have access to CFGR1 except for command 1111b, which is reserved.

8.4.8 Data Output Length

CFGR1 bits (D3 and D2) of the data register select the output data length. The data-length selection is valid for the current I/O cycle (the cycle in which the data is read). The data-length selection, being valid for the current I/O cycle, allows device start-up without losing I/O synchronization. A data length of 8, 12, or 16 bits can be selected. Because the converter has 12-bit resolution, a data length of 12 bits is suggested.

With D3 and D2 set to 00 or 10, the device is in the 12-bit data-length mode and the result of the current conversion is output as a 12-bit serial data stream during the next I/O cycle. The current I/O cycle must be exactly 12 bits long for proper synchronization, even when this means corrupting the output data from a previous conversion. The current conversion is started immediately after the twelfth falling edge of the current I/O cycle.

With bits D3 and D2 set to 11, the 16-bit data-length mode is selected, which allows convenient communication with 16-bit serial interfaces. In the 16-bit mode, the result of the current conversion is output as a 16-bit serial data stream during the next I/O cycle with the four LSBs always reset to 0 (pad bits). The current I/O cycle must be exactly 16 bits long to maintain synchronization even when this means corrupting the output data from the previous conversion. The current conversion is started immediately after the sixteenth falling edge of the current I/O cycle.

With bits D3 and D2 set to 01, the 8-bit data-length mode is selected, which allows fast communication with 8-bit serial interfaces. In the 8-bit mode, the result of the current conversion is output as an 8-bit serial data stream during the next I/O cycle. The current I/O cycle must be exactly eight bits long to maintain synchronization, even when this means corrupting the output data from the previous conversion. The four LSBs of the conversion result are truncated and discarded. The current conversion is started immediately after the eighth falling edge of the current I/O cycle.

Because the D3 and D2 register settings take effect on the I/O cycle when the data length is programmed, there can be a conflict with the previous cycle if the data-word length was changed. This may occur when the data format is selected to be least significant bit first, because at the time the data length change becomes effective (six rising edges of I/O CLOCK), the previous conversion result has already started shifting out. In actual operation, when different data lengths are required within an application and the data length is changed between two conversions, no more than one conversion result can be corrupted and only when it is shifted out in LSB-first format.

8.4.9 LSB Out First

D1 in the CFGR1 controls the direction of the output (binary) data transfer. When D1 is reset to 0, the conversion result is shifted out MSB first. When set to 1, the data is shifted out LSB first. Selection of MSB first or LSB first always affects the next I/O cycle and not the current I/O cycle. When changing from one data direction to another, the current I/O cycle is never disrupted.

8.4.10 Bipolar Output Format

D0 in the CFGR1 controls the binary data format used to represent the conversion result. When D0 is cleared to 0, the conversion result is represented as unipolar (unsigned binary) data. Nominally, the conversion result of an input voltage equal to or less than V_{REF-} is a code with all zeros (000 . . . 0) and the conversion result of an input voltage equal to or greater than V_{REF+} is a code of all ones (111 . . . 1). The conversion result of $(V_{REF+} + V_{REF-})/2$ is a code of a one followed by zeros (100 ...0).

When D0 is set to 1, the conversion result is represented as bipolar (signed binary) data. Nominally, conversion of an input voltage equal to or less than V_{REF-} is a code of a one followed by zeros (100 . . . 0), and the conversion of an input voltage equal to or greater than V_{REF+} is a code of a zero followed by all ones (011 . . . 1). The conversion result of $(V_{REF+} + V_{REF-})/2$ is a code of all zeros (000 . . . 0). The MSB is interpreted as the sign bit. The bipolar data format is related to the unipolar format in that the MSBs are always each other's complement.

Selection of the unipolar or bipolar format always affects the current conversion cycle, and the result is output during the next I/O cycle. When changing between unipolar and bipolar formats, the data output during the current I/O cycle is not affected.

8.4.11 \overline{EOC} Output

Pin 19 outputs the status of the ADC conversion. When programmed as EOC, the output indicates the beginning and the end of conversion. In the reset state, EOC is always high. During the sampling period (beginning after the fourth falling edge of the I/O CLOCK sequence), EOC remains high until the internal sampling switch of the converter is safely opened. The opening of the sampling switch occurs after the eighth, twelfth, or sixteenth I/O CLOCK falling edge, depending on the data-length selection in the input data register. After the EOC signal goes low, the analog input signal can be changed without affecting the conversion result.

The EOC signal goes high again after the conversion is completed and the conversion result is latched into the output data register. The rising edge of EOC returns the converter to a reset state and a new I/O cycle begins. On the rising edge of EOC, the first bit of the current conversion result is on DATA OUT when \overline{CS} is low. When \overline{CS} is toggled between conversions, the first bit of the current conversion result occurs on DATA OUT at the falling edge of \overline{CS} .

8.4.12 Chip-Select Input (\overline{CS})

\overline{CS} enables and disables the device. During normal operation, \overline{CS} should be low. Although the use of \overline{CS} is not necessary to synchronize a data transfer, it can be brought high between conversions to coordinate the data transfer of several devices sharing the same bus.

When \overline{CS} is brought high, the serial-data output is immediately brought to the high-impedance state, releasing its output data line to other devices that may share it. After an internally generated debounce time, I/O CLOCK is inhibited, thus preventing any further change in the internal state.

When \overline{CS} is subsequently brought low again, the device is reset. \overline{CS} must be held low for an internal debounce time before the reset operation takes effect. After \overline{CS} is debounced low, I/O CLOCK must remain inactive (low) for a minimum time before a new I/O cycle can start.

\overline{CS} can interrupt any ongoing data transfer or any ongoing conversion. When \overline{CS} is debounced low long enough before the end of the current conversion cycle, the previous conversion result is saved in the internal output buffer and shifted out during the next I/O cycle.

When \overline{CS} is held low continuously for multiple cycles, the first data bit of the newly completed conversion occurs on DATA OUT on the rising edge of EOC.

NOTE

the first cycle in the series still requires a transition \overline{CS} from high to low. When a new conversion is started after the last falling edge of I/O CLOCK, EOC goes low and the serial output is forced low until EOC goes high again.

When \overline{CS} is toggled between conversions, the first data bit occurs on DATA OUT on the falling edge of \overline{CS} . On each subsequent falling edge of I/O CLOCK after the first data bit appears, the data is changed to the next bit in the serial conversion result until the required number of bits has been output.

8.4.13 Power-Down Features

When command (D7–D4) 1110b is clocked into the input data register during the first four I/O CLOCK cycles, the software power-down mode is selected. Software power down is activated on the falling edge of the fourth I/O CLOCK pulse.

During software power-down, all internal circuitry is put in a low-current standby mode. No conversions is performed. The internal output buffer keeps the previous conversion cycle data results, provided that all digital inputs are greater than $V_{CC} - 0.5\text{ V}$ or less than 0.5 V . The I/O logic remains active so the current I/O cycle must be completed even when the power-down mode is selected. Upon power-on reset and before the first I/O cycle, the converter normally begins in the power-down mode. The device remains in the software power-down mode until a valid input address (other than command 1110b or 1111b) is clocked in. Upon completion of that I/O cycle, a normal conversion is performed with the results being shifted out during the next I/O cycle.

The ADC also has an auto power-down mode. This is transparent to users. The ADC gets into auto power-down within 1 I/O CLOCK cycle after the conversion is complete and resumes, with a small delay, after an active CS is sent to the ADC. The resumption is fast enough to be used between cycles.

9 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

As with most SAR ADCs, the inputs of the TLV2553 are not high-impedance ports. At the start of the sampling phase, the selected input channel experiences a load current, as the internal analog switches close and the sampling capacitor starts to charge (or discharge). This load current decays over time and varies in a nonlinear fashion with respect to input voltage.

The load current is supplied by the input signal source which has non-zero output impedance. As a result, the load current drops non-zero voltage across the output impedance of the signal source creating a time-decaying, nonlinear error between the signal source output and the ADC input. This is called sampling error, and if the sampling error does not decay to less than 1 LSB before the end of the sampling window when the sampling switch opens and conversion begins, the ADC output is inaccurate.

The rate of decay of the sampling error and its nonlinearity over input voltage are highly sensitive to source impedance. In other words, for larger values of source impedance, the sampling error decays more slowly over time, resulting in greater residual error at the end of the sampling window that is also more non-linear over the ADC input voltage range. Nonlinearity in the ADC input translates to nonlinearity or harmonic distortion in the ADC output. Harmonic distortion degrades ADC resolution and translates to a decrease in the ADC's effective number of bits (ENOB). Therefore, driving the ADC input with a low-impedance source is critical for conversion accuracy.

In addition to keeping source impedance as low as possible, TI recommends the following measures for minimizing input sampling error and harmonic distortion associated with the TLV2553 while operating the device at maximum 200-KSPS throughput:

- For AC inputs, the maximum input signal frequency on all channels should be limited to well less than the maximum Nyquist rate of 100 kHz. [Figure 40](#) shows how ENOB degrades as input frequency increases.

$$R_{\text{source}} = 50 \, \Omega \quad f_s = 200 \text{KSPS}$$

Figure 40. ENOB as a Function of Input Signal Frequency

- For DC inputs, ensure that there are no large step-function changes (greater than $V_{\text{REF}} / 4$) between successive input channels in the scanning order at the highest throughput. If possible, it is advisable to scan the input channels so that the difference in the DC voltage levels between any two successive channels is minimized to ensure 12-bit sampling accuracy. For larger voltage changes between channels, higher accuracy can be achieved by reducing the throughput.

Application Information (continued)

- The stability of the ADC reference input voltage, which is a DC signal, is critical for ADC accuracy. The reference source experiences large instantaneous changes in load current during the ADC conversion phase, and therefore, low source impedance is required for excellent load regulation and stability.

9.2 Typical Application

Figure 41 shows a typical application where the TLV2553 is used to acquire multiple AC signals while operating at its maximum sampling rate of 200 KSPS.

Figure 41. Typical Application Block Diagram

9.2.1 Design Requirements

The design is optimized for superior dynamic performance (low harmonic distortion, high ENOB) while the ADC is multiplexing input channels at maximum sampling rate. Of course, the underlying assumption, based on , is that the bandwidths of the input signals are much less than 100 kHz. For example, according to , the TLV2553 provides better than 11.5 ENOB for AC inputs less than 10 kHz.

Typical Application (continued)

9.2.2 Detailed Design Procedure

Good dynamic performance while the ADC is multiplexing inputs at maximum sampling rate requires low source impedance on the input channels being addressed. To make the input source impedance less sensitive to line inductance, especially in cases where the signal sources may be located far away from the ADC, it may be necessary to use operational amplifier buffers located close to the ADC input pins.

The procedure for estimating the maximum tolerable value of input source impedance on a given channel for achieving the desired ENOB (for example ENOB > 11.5) in a multiplexed application is as follows:

1. Using a low impedance signal source, apply a full-scale sinusoidal signal of suitably low frequency to the ADC input channel of interest, CHx.
2. Using a second low impedance source, apply a full-scale sinusoid that has the same frequency as the signal on CHx but is 180° out-of-phase, to a second ADC input channel, CHy, that will serve as the control element in the experiment.
3. Initiate conversions with the ADC continuously multiplexing between CHx and CHy in each conversion cycle.
4. Rearrange the output data by channel, and for each of the two channels, compute SINAD from its FFT and estimate ENOB for that channel as $ENOB = (SINAD[dB] - 1.76) / 6.02$.
5. Increase the series resistance on CHx by a discrete amount and repeat steps 1 through 5 until the ENOB of CHx has degraded sufficiently relative to CHy (which should remain unchanged).

The external 1-nF decoupling capacitors (recommend C0G/NP0 type for constant capacitance versus voltage) on the input channels are required for supplying the instantaneous change in the ADC's load current demand during the sampling phase after an input channel is selected. In other words, the decoupling capacitor effectively reduces the output impedance of the source at high frequencies.

Similarly, the reference pin also requires decoupling for low-output impedance at high frequency. However, the larger magnitude of reference pin load currents during the ADC conversion phase necessitates a decoupling capacitor of a much higher value. The extra ESR (2.5 Ω) is required for stabilizing the OPA320 output as it drives the 10-μF load.

The OPA320 is a wide-band, low-noise, low-power operational amplifier that is unity gain stable and can operate on a single 5-V system supply while supporting rail-to-rail signal swing at its input and output. These properties make it an ideal choice for being used as a high-precision (stable, low-noise) reference buffer that has enough loop gain over frequency to support low-output impedance over a wide bandwidth.

9.2.3 Application Curve

was generated by sweeping R_{source} from 50 Ω to 1 kΩ following the procedure detailed in .

$$f_{IN} = 1 \text{ kHz} \quad f_s = 200 \text{ KSPS}$$

Figure 42. ENOB as a Function of Input Source Impedance

10 Power Supply Recommendations

The TLV2553 is designed to operate from a single power supply voltage from 2.7 V to 5.5 V. The ADC supply voltage must be well-regulated. A 1- μ F ceramic decoupling capacitor is required and must be placed as close as possible to the device to minimize inductance along the load current path.

Many modern microcontrollers have interfaces that support only up to 3.3-V logic levels, which is incompatible with the TLV2553 when the device is operated on a 5-V power supply. In such cases, 5-V to 3.3-V digital level translators may be used to facilitate communication between the TLV2553 and the microcontroller host.

11 Layout

11.1 Layout Guidelines

- All decoupling capacitors must be located as close as possible to the loads they are supplying.
- TI recommends large copper fill areas or thick traces wherever possible to provide low inductance current paths between decoupling capacitors and their loads
- Ensure that there are no vias or discontinuities in the forward or return current paths that can cause the current loop area and therefore the loop inductance to increase.
- For high-frequency current paths routed across PCB layers, multiple vias can be placed close together (but not obstructing the current path) to lower inductance.

11.2 Layout Example

Figure 43. Layout Example Schematic

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=100ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

⁽⁶⁾ Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

IMPORTANT NOTICE

Texas Instruments Incorporated (TI) reserves the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete.

TI's published terms of sale for semiconductor products (<http://www.ti.com/sc/docs/stdterms.htm>) apply to the sale of packaged integrated circuit products that TI has qualified and released to market. Additional terms may apply to the use or sale of other types of TI products and services.

Reproduction of significant portions of TI information in TI data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such reproduced documentation. Information of third parties may be subject to additional restrictions. Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyers and others who are developing systems that incorporate TI products (collectively, "Designers") understand and agree that Designers remain responsible for using their independent analysis, evaluation and judgment in designing their applications and that Designers have full and exclusive responsibility to assure the safety of Designers' applications and compliance of their applications (and of all TI products used in or for Designers' applications) with all applicable regulations, laws and other applicable requirements. Designer represents that, with respect to their applications, Designer has all the necessary expertise to create and implement safeguards that (1) anticipate dangerous consequences of failures, (2) monitor failures and their consequences, and (3) lessen the likelihood of failures that might cause harm and take appropriate actions. Designer agrees that prior to using or distributing any applications that include TI products, Designer will thoroughly test such applications and the functionality of such TI products as used in such applications.

TI's provision of technical, application or other design advice, quality characterization, reliability data or other services or information, including, but not limited to, reference designs and materials relating to evaluation modules, (collectively, "TI Resources") are intended to assist designers who are developing applications that incorporate TI products; by downloading, accessing or using TI Resources in any way, Designer (individually or, if Designer is acting on behalf of a company, Designer's company) agrees to use any particular TI Resource solely for this purpose and subject to the terms of this Notice.

TI's provision of TI Resources does not expand or otherwise alter TI's applicable published warranties or warranty disclaimers for TI products, and no additional obligations or liabilities arise from TI providing such TI Resources. TI reserves the right to make corrections, enhancements, improvements and other changes to its TI Resources. TI has not conducted any testing other than that specifically described in the published documentation for a particular TI Resource.

Designer is authorized to use, copy and modify any individual TI Resource only in connection with the development of applications that include the TI product(s) identified in such TI Resource. NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER TI INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT OF TI OR ANY THIRD PARTY IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information regarding or referencing third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of TI Resources may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI RESOURCES ARE PROVIDED "AS IS" AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS. TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY DESIGNER AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Unless TI has explicitly designated an individual product as meeting the requirements of a particular industry standard (e.g., ISO/TS 16949 and ISO 26262), TI is not responsible for any failure to meet such industry standard requirements.

Where TI specifically promotes products as facilitating functional safety or as compliant with industry functional safety standards, such products are intended to help enable customers to design and create their own applications that meet applicable functional safety standards and requirements. Using products in an application does not by itself establish any safety features in the application. Designers must ensure compliance with safety-related requirements and standards applicable to their applications. Designer may not use any TI products in life-critical medical equipment unless authorized officers of the parties have executed a special contract specifically governing such use. Life-critical medical equipment is medical equipment where failure of such equipment would cause serious bodily injury or death (e.g., life support, pacemakers, defibrillators, heart pumps, neurostimulators, and implantables). Such equipment includes, without limitation, all medical devices identified by the U.S. Food and Drug Administration as Class III devices and equivalent classifications outside the U.S.

TI may expressly designate certain products as completing a particular qualification (e.g., Q100, Military Grade, or Enhanced Product). Designers agree that it has the necessary expertise to select the product with the appropriate qualification designation for their applications and that proper product selection is at Designers' own risk. Designers are solely responsible for compliance with all legal and regulatory requirements in connection with such selection.

Designer will fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of Designer's non-compliance with the terms and provisions of this Notice.
